## Defining the simulations to evaluate Fishing Intensity

## Allan Hicks

Management Strategy Advisory Board May 9-11, 2017

IPHC-2017-MSAB09-07

## Purpose

- Discuss the framework of the closed-loop simulations
- Define the inputs for the closed-loop simulations to investigate Scale of the harvest policy

1. The Operating Model (OM) and Scenarios
2. Generation of data for the Estimation Model (EM)
3. The EM's to use
4. The details of the Harvest Strategy to simulate
5. Management Procedures to simulate and evaluate

- Fishing Intensity (FI) metric
- Values for the FI metric
- Control Rule
- Discuss some potential ways to present results

## Review of AM093

- Harvest Policy outdated and a need to remove the blue line reference
- Provide a

approach to setting catch levels

Report of the $93^{\text {rd }}$ Session of the IPHC Annual Meeting (AM093)

Victoria, British Columbia, Canada, 23-27 January 2017

## Review of AM093

- Noted a SPR-based harvest policy
- Separate Scale and Distribution
- Account for mortality of all sizes from all sources

## Review of AM093

## - Status-quo SPR is an interim "hand rail"

- $\mathrm{SPR}=46 \%$
- Average SPR from last three years

## Review of AM093

- Use MSE to evaluate options for a modified harvest policy that separates Scale and Distribution, and accounts for all mortality
- Evaluate SPR values that are robust to possible bycatch scenarios

## Simulation Framework

Cannot control

- Operating Model (OM)
- Monitoring (Data Generation)
- Estimation Model (EM)
- Harvest Strategy
Operating Model
Population
- Stock dynamics
- Parameters
- Variability

## Operating Model (OM)

- A representation of the population and the fishery
- Produces the numbers-at-age, accounting for mortality and any other important processes
- Incorporates uncertainty in processes
- Complexity driven by
- The questions being asked
- The knowledge to parameterize
- The time available to develop and run

## OM modeling platforms

- Use Stock Synthesis and current assessment setup
- Currently conditioned to data
- Using my own model will require additional time
- Coding
- Testing
- Conditioning

## OM specifications

- Coastwide or Fleets-as-areas
- Five fleets plus a survey in coastwide model

1. Commercial
2. Wastage
3. Bycatch
4. Sport
5. Personal
6. Survey

## Should we use fleets-as-areas?

- Need to distribute directed fishery catch to areas
- Does not treat non-commercial catch as fleets
- Need to also distribute survey observations
- Slower run times
- Use all 4 assessment models as OM

## OM uncertainty

- Uncertainty is estimated when fitting to data
- Uncertainty can be assigned to fixed parameters
- Multiple models provide structural uncertainty

## Monitoring (Data Generation)

- Code to simulate observations from the OM that is used by the Estimation Model (EM)
- Data to generate are determined by the EM used and the structure of the harvest strategy

## Estimation Model (EM)

- Mimics the model and processes used to estimate quantities needed for the harvest strategy
- IPHC uses an ensemble of four assessment models
- Produces a decision table with one row representing the current harvest policy
- The EM provides additional uncertainty to the variability in the OM
- Can also be set up for misspecification

## EM methods

- Perfect Information
- Quantities needed for harvest strategy are know exactly
- Simulate Error
- Take the abundance from the OM and apply error to it
- Single stock assessment
- An assessment model using generated data
- Ensemble of models
- Multiple assessment models combined

## Harvest Strategy

- A coastwide Fishing Intensity
- A control rule (i.e., 30:20)
- Catch sharing plans to allocate catch to sectors

## Harvest Strategy

- Do not need to distribute the TCEY to evaluate Fishing Intensity
- Use coastwide models
- Make assumptions about allocation to five fleets

## Can we distribute TCEY?

- With a coastwide model, we can pseudo-distribute the TCEY to Regulatory Areas
- Partition TCEY into sectors based on Area
- Evaluate different Fishing Intensities among areas

## Can we distribute TCEY?

$$
\operatorname{TCEY}_{A}=\operatorname{TCEY} \frac{\rho_{A} \times F_{A}}{\sum_{A} \rho_{A} \times F_{A}}
$$

- The symbol $\rho_{A}$, formerly know as apportionment
- The proportion of the O32 stock in each Regulatory Area
- $F_{A}$ is the relative fishing intensity in each Area
- If fishing intensity is the same for all Areas, then $F_{A}=1$

## Psuedo-previous harvest policy

- $F_{A}$ can be based on $16.125 \%$ and $21.5 \%$, or anything else
- The problem is that there is not feedback from the population
- $\rho_{A}$ is difficult without a multi-area model
- Could possibly sample proportions from past realizations
- Could indicate how TCEY is distributed and inform sector specific catches
- Would introduce additional variability

## Coastwide or pseudo-areas?

Coastwide

| Pros | Cons |
| :---: | :---: |
| Simple | Won't provide for <br> Fleets-As-Areas <br> OM |
| Focused on <br> coastwide FI | No relative <br> difference <br> between Areas |
|  | Assumptions to <br> split TCEY to <br> sectors |

Won't provide insight into Areaspecific objectives

## Pseudo-Area

| Pros | Cons |
| :---: | :---: |
| Provide for Fleets- <br> As-Areas OM | More complicated. <br> (how is TCEY <br> distributed) |
| Can investigate <br> relative FI in Areas | No feedback from <br> population in those <br> Areas |
| Split TCEY into <br> sectors for each <br> Area | Many assumptions <br> when distributing <br> TCEY and splitting <br> in each Area |
|  | Won't provide <br> insight into Area- <br> specific objectives |

## Should we distribute TCEY?

- Not a lot of benefit without a multi-area model
- No feedback from the population
- Assumptions to distribute TCEY may add more variability than necessary (or may get it wrong)
- We should deal with distribution appropriately using a multi-area operating model
- Benefits
- More realistic uncertainty
- Determine sector catches more realistically within areas

## My suggestions for the framework

## Operating Model (OM)

- Stock Synthesis: Coastwide Model or Fleets-As-Areas?
- Use multiple models (e.g., two coastwide)
- Five fleets, as in assessment models
- TCEY assigned as defined in Scenarios
- Uncertainty incorporated via two methods (Scenarios)
- Parameter uncertainty from the estimated assessments
- Structural uncertainty
- Two models and other parameters as defined by MSAB

## My suggestions for the framework

Estimation Models (EM)

- Perfect Information
- as a reference
- Ensemble of two coastwide models
- If not too time-consuming
- Otherwise
- a single assessment with additional error added
- simply simulate error

## My suggestions for the framework

## Harvest Strategy

- A coastwide Fishing Intensity
- A control rule (e.g., 30:20)
- Catch assigned to sectors based on past and future expectations (with variability)

## My suggestions for the framework

## Data Generation

| Data | Sexes | Prob Distn | Bias?* | Uncertainty |
| :--- | :--- | :--- | :--- | :--- |
| Survey NPUE | Combined | Lognormal | No | From Assessment |
| Survey age comp | Separate | Dirichlet | Selectivity? | From Assessment |
| Survey U26 age comp | Separate | Dirichlet | Selectivity? | From Assessment |
| Fishery WPUE | Combined | Lognormal | q? | From Assessment |
| Fishery age comp | Combined | Dirichlet | Selectivity? | From Assessment |
| Bycatch age comp | Combined | Dirichlet | Selectivity? | From Assessment |
| Sport age comp | Combined | Dirichlet | Selectivity? | From Assessment |

[^0]
## Scenarios

- Uncertainty we cannot or choose not to control
- Not part of a management procedure
- Goal is to develop a management strategy robust to these uncertainties

# Scenarios (Decisions) 

Process Uncertainty
Natural Mortality (M) From assessment

| Recruitment | Random, lognormal deviations, varia |
| :--- | :--- |
| Size-at-age | Trend in size-at-age (random walk) |

Maturity-at-age
Steepness
Regime Shifts
Fishery Selectivity
Survey Selectivity
WPUE catchability
Survey catchability
TCEY to sectors (e.g., bycatch) See next slides
Prop of TCEY taken
Based on historical distribution, all sectors

## Allocate simulated TCEY to sectors

- First determine how the total mortality (TM, catch) relates to the TCEY
- I can look at recent total utilization
- Will need to make assumptions about U26 and O26
- Is there a maximum catch or minimum catch?
- Then allocate TM to sectors
- Using recent observations and future expectations
- Include variability

## TM to sectors

- Once I have determined coastwide catch from the TCEY
- Allocate catch to sectors

## TM to sectors

- Define proportions of TM for each sector
- Can depend on total TM
- Sport, Personal, Bycatch a higher \% when catch low
- Wastage a function of Commercial
- Can incorporate variability
- Scenarios for bycatch, etc.
- For fleets-as-areas
- First distribute to areas, then to sectors within areas

## TM to sectors

- Determining TM for each sector
- Personal ~N(1.2 Mlbs, $\sigma=0.2$ ) then determined as \%
- Bycatch(\%) $=0.4346-0.067 \ln (T M)$
- Intercept ~ N(0.4346, $\sigma=$ ???)
- Slope ~ N(0.067, $\sigma=? ? ?)$

Bycatch since 1998

## TM to sectors

- Determin

Sport catch since 1998

- Persona
- Bycatch
- With
- Sport

- $11 \%$ when $\mathrm{TM} \geq 60 \mathrm{Mlbs}$
- 33.02-0.367(TM) when TM < 60Mlbs
- TM=60, Sport\%=11\%
- TM=40, Sport\%=18.3\%

## TM to sectors (Decisions)

- Determining TM for each sector
- Personal ~N(1.2 Mlbs, $\sigma=0.2$ ) then determined as \%
- Bycatch(\%) = 0.4346-0.067In(TCEY)
- With variation
- Sport(\%) = 33.02-0.367(TCEY) with a minimum of $11 \%$
- With variation
- Commercial + Wastage is remaining \%
- Wastage(\%) is a function of O32 (age proxy)

## TM to sectors (Decisions)

- Determining Total Mortality (catch) for each sector

Predicted Percentages

## Management Procedures

- We will consider two management procedures to evaluate concurrently
- Fishing Intensity
- Control Rule

## Fishing Intensity metrics

## What we want in a metric

- As fishing effort increases, the fishing intensity metric also increases appropriately
- Applies to simple as well as complex models
- Metric changes with changes in selectivity, and captures systematic changes in selectivity
- Easy to compute
- A scale that is easy to understand

## Exploitation Rate (U)

- Catch divided by a exploitable biomass
- For a single fleet
- A summary biomass is used when multiple fleets have different selectivities
- Ignores difference between fisheries and impacts on size, age, and sex
- Not a useful metric when more than one fleet
- Not consistent with changing selectivity

## Instantaneous Fishing Mortality (F)

- Fishing mortality on most highly selected age, size, and sex
- Catch is a function of $F$ and selectivity
- A change in selectivity changes the meaning of $F$
- Scale not easily interpreted
- Is a useful parameter for modelling, but not so much for fishing intensity

## Fishing Ratio

 Biomass of fish that die due to fishing
## Biomass of fish that die due to natural causes

- A useful metric to gauge current impacts due to fishing
- Could be used to set a maximum impact in a given year
- Does not directly relate to spawners

## Spawning Exploitation Rate (SER)

- A measure of reduction in SB due to fishing
- Called Annual Foregone Reproduction by Mace (1996)
- SRB suggestion to consider this metric

$$
S E R=1-\frac{S B_{\text {fishing }, y}}{S B_{\text {noFishing }, y}}
$$

- Does not directly account for mortality of smaller fish
- May be sensitive to shifts in selectivity
- May be interesting to report annually

# Relative Foregone Yield (RFY) 

Equilibrium yield with current conditions and FI
Max equilibrium yield with current conditions

- Percentage of MSY (given current conditions)
- Related to "Pretty Good Yield" (Hilborn 2010)
- Not certain which side of the yield curve
- May be useful to report and monitor, or as a performance metric

## Spawning Potential Ratio (SPR)

- A measure of the effect of fishing on the long-term reproductive potential of the stock
- If you were to fish a this exact rate, what percentage of the spawning potential would remain
- $\operatorname{SPR}=100 \%$ is no fishing
- $\operatorname{SPR}=40 \%$ is a $60 \%$ reduction
- Commonly used for management

$$
S P R=\frac{\widehat{S B P R}_{F}}{\widehat{S B P R}}
$$

- Currently used in IPHC interim HP

## Equilibrium Relative Spawning Biomass (ERSB)

- Uses current conditions to calculate equilibrium spawning biomass
- Similar to SPR, except not per-recruit
- Can be calculated directly from SPR and steepness
- May be a better metric to use for the control rule

$$
E R S B=\frac{\widetilde{S B}_{F}}{\widetilde{S B}_{\text {noF }}}
$$

$$
E R S B=\frac{4 h S P R+h-1}{5 h-1}
$$

## A comparison of SPR and ERSB

- Steepness = 0.75

## A comparison of fishing metrics

$\left.\begin{array}{|l|l|l|l|l|l|l|l|l|}\hline \text { Metric } & \begin{array}{l}\text { Multiple } \\ \text { fisheries } \\ \text { and } \\ \text { areas }\end{array} & \begin{array}{l}\text { Equili- } \\ \text { brium }\end{array} & \begin{array}{l}\text { Easy } \\ \text { to } \\ \text { calc- } \\ \text { ulate }\end{array} & \begin{array}{l}\text { Easy } \\ \text { to } \\ \text { inter- } \\ \text { pret }\end{array} & \text { Range } & \begin{array}{l}\text { Account } \\ \text { for } \\ \text { fishing } \\ \text { mortality }\end{array} & \begin{array}{l}\text { Current } \\ \text { conditons } \\ \text { or regime }\end{array} & \\ \hline \text { on all } \\ \text { sizes }\end{array}\right]$

## Management Procedures for Fl (Decisions)

- Which metric(s) to use to set scale?
- I suggest $F_{\text {SPR }}$
- Possibly report FR, SER, and RFY as performance metrics
- Which values for the metric(s)
- I suggest $S P R=0.25$ to 0.60 by 0.05
- Also SPR = 0.46 for status quo
- Additional values that I feel would fill in the results

## Control Rule

- Threshold is 30\%
- Limit is $20 \%$
- Adjust FI
- What are the appropriate threshold \& limit?
- How should RSB be calculated?

## Control Rule relationship with FI \& ERSB

Equilibrium concepts
(reference points)

- ERSB is a function of SPR and defines a target
- The target should be greater than the threshold
- The threshold is a status you want to be above most of the time
- Limit is a status you
 really want to avoid

## Control Rule current status

$$
R S B=\frac{S B_{\text {current }}}{S B_{0}}
$$

- RSB is not a clear concept when there are regime shifts and changing biology
$-\mathrm{SB}_{0}$ is defined on static recruitment and biology
- Not reflective of current conditions
- Definition of $\mathrm{SB}_{0}$ could result in poor stock status without fishing (e.g., reduction in size-at-age)

## Control Rule current status

- For consistency with SPR and ERSB, RSB should be calculated using current conditions
- RSB should equal 1 if no fishing has occurred
- $\mathrm{SB}_{\text {current }}$ depends on past recruitment, thus denominator should also

## Control Rule current status

## Dynamic RSB and $\mathrm{SB}_{0}\left(\mathrm{dRSB} \& \mathrm{dSB}_{0}\right)$

- The spawning biomass if no fishing occurred on current cohorts
- Uses recent recruitment deviations and biology for the numerator and denominator
- By definition, ranges from 0 to 1

$$
d R S B=\frac{S B_{\text {current }}}{d S B_{0}}
$$

## Control Rule summary <br> - ERSB and SPR

- Consistent equilibrium concepts that account for current conditions
- Define a target
- Can be used to help define threshold, limit
- Can be calculated in "short" assessment models
- dRSB
- A calculation for current RSB that is consistent with ERSB and SPR
- dRSB is expected to fluctuate around the target ERSB

## Control Rule decisions

- My suggestions
- Control Rule scale fishing intensity (FSPR)
- Use a 30:20 control rule, but with dRSB
- Use a 25:15 control rule with dRSB for comparison
- Possibly evaluate a case without a control rule

## Control Rule additional thoughts

- We have an objective and performance metric related to the control rule
- More about this later
- I would like to discuss dRSB with the SRB before evaluating too many control rules

From 2016 Assessment

| Year | RSB | dRSB |
| :--- | ---: | ---: |
| 2014 | $\sim 41 \%$ | $\sim 33 \%$ |
| 2015 | $\sim 41 \%$ | $\sim 34 \%$ |
| 2016 | $\sim 42 \%$ | $\sim 36 \%$ |
| 2017 | $\sim 43 \%$ | $\sim 36 \%$ |

## Presenting results

# Presenting Results 

- A complicated figure to show the trade-offs (from Pacific hake)
- Trade-offs are typically between
- Conservation
- Yield
- Stability in yield

AAV 90\% interval

## Summary

- Framework
- OM, Data, EM, Harvest Strategy
- Scenarios
- Variability in simulations
- TCEY to sectors
- Fishing Intensity
- Control Rule

[^0]:    *Bias is whether there is a difference between generated data and EM
